

# Lecture 4: Data Structures I

COMP526: Efficient Algorithms

Updated: October 15, 2024

Will Rosenbaum  
University of Liverpool

# Announcements

---

## 1. Second Quiz, due Friday

- Similar format to before
  - One question, select all correct answers
  - 20 minute time limit
- Covers asymptotic (Big-O) notation
  - Lectures 03 and 04
  - Relevant reading from **CLRS**
- Quiz is **closed resource**
  - No books, notes, internet, etc.
  - Do not discuss until after submission deadline (Friday night, after midnight)

## 2. Programming Assignment 1: Discuss on Thursday

- Due 13 November

## 3. Attendance Code:

# Meeting Goals

---

- Finish discussion of asymptotic notation
- Introduce Abstract Data Types:
  - Stack
  - Queue
  - Priority Queue
- Discuss array-backed and linked list-backed implementations of Stacks and Queues
- Introduce amortized analysis

# Asymptotic Notation

# From Last Time

## Definition

Suppose  $f$  and  $g$  are functions from  $\mathbf{N}$  to  $\mathbf{R}^+$ . Then we say that  $f = O(g)$  (read:  $f$  is big  $O$  of  $g$ ) if there exist constants  $N_0 \in \mathbf{N}$  and  $C \in \mathbf{R}$  such that for all  $n \in \mathbf{N}$

$$n \geq N_0 \implies f(n) \leq Cg(n).$$

Equivalently,  $f = O(g) \iff \limsup \frac{f(n)}{g(n)} < \infty$

## Proposition

Suppose  $f, f_1, f_2, g, g_1, g_2, h$  are functions and  $a$  is any constant. Then:

1.  $(\forall n f(n) \leq a) \implies f = O(1)$
2.  $(\forall n f(n) \leq g(n)) \implies f = O(g)$
3.  $f = O(g) \implies a \cdot f = O(g)$
4.  $f = O(g)$  and  $g = O(h) \implies f = O(h)$
5.  $f = O(h)$  and  $g = O(h) \implies f + g = O(h)$
6.  $f_1 = O(g_1)$  and  $f_2 = O(g_2) \implies f_1 \cdot f_2 = O(g_1 \cdot g_2)$

# Variations of O

---

- $f = \Theta(g)$  if  $f = O(g)$  and  $g = O(f)$ 
  - Example:  $4n^2 + 3n + 7 = \Theta(n^2)$
- $f = \Omega(g)$  if  $g = O(f)$ 
  - Example:  $0.01n^2 - 7n = \Omega(n^2)$
- $f = o(g)$  if for every  $\varepsilon > 0$ , there exists  $N_0$  such that  $n \geq N_0 \implies \frac{f(n)}{g(n)} < \varepsilon$ .
  - Equivalently:  
$$f = o(g) \iff \lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = 0$$
  - Example:  $n^{1.999} = o(n^2)$
- $f = \omega(g)$  if  $g = o(f)$ 
  - Example:  $0.01n^{2.01} = \omega(n^2)$

# Variations of O

---

- $f = \Theta(g)$  if  $f = O(g)$  and  $g = O(f)$ 
  - Example:  $4n^2 + 3n + 7 = \Theta(n^2)$
- $f = \Omega(g)$  if  $g = O(f)$ 
  - Example:  $0.01n^2 - 7n = \Omega(n^2)$
- $f = o(g)$  if for every  $\varepsilon > 0$ , there exists  $N_0$  such that  $n \geq N_0 \implies \frac{f(n)}{g(n)} < \varepsilon$ .
  - Equivalently:  
$$f = o(g) \iff \lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = 0$$
  - Example:  $n^{1.999} = o(n^2)$
- $f = \omega(g)$  if  $g = o(f)$ 
  - Example:  $0.01n^{2.01} = \omega(n^2)$

**Mnemonic** for  
Variations

Big-O	(in)equality
$\omega$	$>$
$\Omega$	$\geq$
$\Theta$	$\approx$
$O$	$\leq$
$o$	$<$

# Variations of O

- $f = \Theta(g)$  if  $f = O(g)$  and  $g = O(f)$ 
  - Example:  $4n^2 + 3n + 7 = \Theta(n^2)$
- $f = \Omega(g)$  if  $g = O(f)$ 
  - Example:  $0.01n^2 - 7n = \Omega(n^2)$
- $f = o(g)$  if for every  $\varepsilon > 0$ , there exists  $N_0$  such that  $n \geq N_0 \implies \frac{f(n)}{g(n)} < \varepsilon$ .
  - Equivalently:  
$$f = o(g) \iff \lim_{n \rightarrow \infty} \frac{f(n)}{g(n)} = 0$$
  - Example:  $n^{1.999} = o(n^2)$
- $f = \omega(g)$  if  $g = o(f)$ 
  - Example:  $0.01n^{2.01} = \omega(n^2)$

## Mnemonic for Variations

Big-O	(in)equality
$\omega$	$>$
$\Omega$	$\geq$
$\Theta$	$\approx$
$O$	$\leq$
$o$	$<$

## More Properties

- $f_1 = O(g_1)$  and  $f_2 = o(g_2) \implies f_1 \cdot f_2 = o(g_1 \cdot g_2)$
- $f_1 = \Omega(g_1)$  and  $f_2 = \omega(g_2) \implies f_1 \cdot f_2 = \omega(g_1 \cdot g_2)$

# Interpretation

---

Suppose:

- two algorithms  $A$  and  $B$  for solving the same problem
- running time of  $A$  is  $f$ , running time of  $B$  is  $g$
- $f = o(g)$

Consider running  $A$  on a **slow** machine  $M_1$  and  $B$  on a **fast** machine  $M_2$ .  
Then: regardless of how much slower  $M_1$  is than  $M_2$ , for *sufficiently large* inputs,  $A$  will complete faster than  $B$ .

# Interpretation

---

Suppose:

- two algorithms  $A$  and  $B$  for solving the same problem
- running time of  $A$  is  $f$ , running time of  $B$  is  $g$
- $f = o(g)$

Consider running  $A$  on a **slow** machine  $M_1$  and  $B$  on a **fast** machine  $M_2$ .  
Then: regardless of how much slower  $M_1$  is than  $M_2$ , for *sufficiently large* inputs,  $A$  will complete faster than  $B$ .

**The Moral.** Efficient *algorithms* are better than faster hardware.

- little- $o$  notation gives the “right” abstraction to formalize this relationship

# Common Orders of Growth

---

**Named** orders of growth:

name	asymptotic growth
constant	$O(1)$
logarithmic	$O(\log n)$
polylogarithmic	$O(\log^c n)$
linear	$O(n)$
almost linear	$O(n \log^c n)$
quadratic	$O(n^2)$
polynomial	$O(n^c)$
exponential	$O(c^n)$

# Common Orders of Growth

---

**Named** orders of growth:

name	asymptotic growth
constant	$O(1)$
logarithmic	$O(\log n)$
polylogarithmic	$O(\log^c n)$
linear	$O(n)$
almost linear	$O(n \log^c n)$
quadratic	$O(n^2)$
polynomial	$O(n^c)$
exponential	$O(c^n)$

**Relationships**

---

Between classes:

For all  $a, b > 0$

- $a = o(\log^b n)$
- $\log^a n = o(n^b)$
- $n^a = o(b^n)$

# Common Orders of Growth

---

**Named** orders of growth:

name	asymptotic growth
constant	$O(1)$
logarithmic	$O(\log n)$
polylogarithmic	$O(\log^c n)$
linear	$O(n)$
almost linear	$O(n \log^c n)$
quadratic	$O(n^2)$
polynomial	$O(n^c)$
exponential	$O(c^n)$

**Relationships**

---

Between classes:

For all  $a, b > 0$

- $a = o(\log^b n)$
- $\log^a n = o(n^b)$
- $n^a = o(b^n)$

---

Within classes:

For all  $a, b, a < b$

- $\log^a n = o(\log^b n)$
- $n^a = o(n^b)$
- $a^n = o(b^n)$

# Example

---

## Example

Compare the asymptotic growth of the following functions:

1.  $f(n) = 2n^2 + 2^{n/2}$
2.  $g(n) = \log^2 n + \sqrt{n}$
3.  $h(n) = n + n \log n + n^{3/2}$

# Linear ADTs and Data Structures

# Abstract Data Types and Data Structures

---

## Abstract Data Types (ADTs)

An **abstract data type** gives a formal specification of a task to be performed:

- List of supported operations (syntax)
- The effects of applying the operations (semantics)

# Abstract Data Types and Data Structures

---

## Abstract Data Types (ADTs)

An **abstract data type** gives a formal specification of a task to be performed:

- List of supported operations (**syntax**)
- The effects of applying the operations (**semantics**)

## Data Structures

A **data structure** specifies

- **how** data is represented
- **how** the supported operations are performed (i.e., what algorithms are used)
- what are the **costs** of the operations

# Abstract Data Types and Data Structures

---

## Abstract Data Types (ADTs)

An **abstract data type** gives a formal specification of a task to be performed:

- List of supported operations ([syntax](#))
- The effects of applying the operations ([semantics](#))

**Question.** Why is it useful to separate ADTs from Data Structure?

- Can swap different data structures for same ADT
  - applications *using* the functionality will not be broken
  - different data structures may be more efficient in some applications
- Better abstractions
- Generic lower bounds

## Data Structures

A **data structure** specifies

- **how** data is represented
- **how** the supported operations are performed (i.e., what algorithms are used)
- what are the **costs** of the operations

# The Stack ADT

---

## Stacks, Intuitively

Goal: to store a *collection* of elements

- elements arranged as in a stack of books
- can only access top-most element:
  - put a new book on the stack
  - look at the top-most book
  - remove the top-most book

# The Stack ADT

---

## Stacks, Intuitively

Goal: to store a *collection* of elements

- elements arranged as in a stack of books
- can only access top-most element:
  - put a new book on the stack
  - look at the top-most book
  - remove the top-most book

## Stacks, Formally

- $S$  is the state of the stack, initially  $S = \emptyset$
- $S.PUSH(x) : S \mapsto Sx$
- $S.TOP() : \text{returns } x_{n-1}$  where  $S = x_0x_1 \cdots x_{n-1}$
- $S.POP() : Sx \mapsto S$ , returns  $x$
- $S.EMPTY()$  returns  $TRUE \iff S = \emptyset$

# The Stack ADT

---

## Stacks, Intuitively

Goal: to store a *collection* of elements

- elements arranged as in a stack of books
- can only access top-most element:
  - put a new book on the stack
  - look at the top-most book
  - remove the top-most book

## Tons of Applications!

- Executing programs (call stack)
- Parsing/evaluating arithmetic expression
- Syntax checking (parenthesis)
- ...

## Stacks, Formally

- $S$  is the state of the stack, initially  $S = \emptyset$
- $S.PUSH(x) : S \mapsto Sx$
- $S.TOP() : \text{returns } x_{n-1}$  where  $S = x_0x_1 \cdots x_{n-1}$
- $S.POP() : Sx \mapsto S$ , returns  $x$
- $S.EMPTY()$  returns  $TRUE \iff S = \emptyset$

# Try It Yourself!

---

## PollEverywhere Question

What is the result of calling TOP() after the following sequence stack operations:

PUSH(1)

PUSH(2)

PUSH(3)

POP()

PUSH(4)

PUSH(5)

POP()

PUSH(6)

POP()

POP()

PUSH(4)

PUSH(5)

POP()

PUSH(6)

POP()

POP()

# Linked List Backed Stack Implementation

---

## Idea

- Store each element in a NODE
- Each NODE stores
  - the value of an element in the stack
  - a *reference* to the NODE storing the next element

```
1: class NODE
2:   datavalue
3:   NODE next
4: end class
```

*ignores empty stack condition*

```
1: class LISTSTACK
2:   NODE head
3:   procedure PUSH(x)
4:      $n \leftarrow$  new NODE
5:      $n.data \leftarrow x$ 
6:      $n.next \leftarrow$  head
7:     head  $\leftarrow n$ 
8:   end procedure
9:   procedure POP
10:     $n \leftarrow$  head
11:    head  $\leftarrow n.next$ 
12:    return  $n.data$ 
13:  end procedure
14:  procedure TOP
15:    return head.data
16:  end procedure
17: end class
```

# Issues with Linked List Stacks

---

## Issues

- NODES waste space
  - must store reference for each entry
- Following chains of reference is costly
  - memory access is **non-local**
  - **sequential** memory access is more efficient

```
1: class LISTSTACK
2:   NODE head ← ∅
3:   procedure PUSH(x)
4:     n ← new NODE
5:     n.data ← x
6:     n.next ← head
7:     head ← n
8:   end procedure
9:   procedure POP
10:    n ← head
11:    head ← n.next
12:    return n.data
13:  end procedure
14:  procedure TOP
15:    return head.data
16:  end procedure
17: end class
```

# Arrays as ADTs

---

*Informally*, arrays are indexed lists of elements:

$$a = \begin{array}{|c|c|c|c|c|c|c|c|c|} \hline 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ \hline l & i & v & e & r & p & o & o & l \\ \hline \end{array}$$

**Array Operations** (ADT):

- **create** an array of size  $n$
- **get** the element at index  $i$ :
  - $a[4]$  returns  $r$
- **set** the value at index  $i$  to a prescribed value
  - $a[5] \leftarrow c$

**Array Operation Costs** (Data Structure)

- **create** an array of size  $n$  has cost  $O(n)$
- **get** and **set** have cost  $O(1)$

# Array Backed Stack Implementation

---

## Idea:

- Store elements in the stack in an array
  - access array values by *index*
  - neighboring values at adjacent indices
    - ⇒ sequential access
- Only overhead: store index of head (top)

```
1: class ARRAYSTACK
2:    $a \leftarrow$  new array
3:   head  $\leftarrow$  0
4:   procedure PUSH(x)
5:      $a[\text{head}] \leftarrow x$ 
6:     head  $\leftarrow$  head + 1
7:   end procedure
8:   procedure POP
9:     head  $\leftarrow$  head - 1
10:    return  $a[\text{head}]$ 
11:  end procedure
12:  procedure TOP
13:    return  $a[\text{head} - 1]$ 
14:  end procedure
15: end class
```

# Array Backed Stack Implementation

---

## Idea:

- Store elements in the stack in an array
  - access array values by *index*
  - neighboring values at adjacent indices
    - ⇒ sequential access
- Only overhead: store index of head (top)

```
1: class ARRAYSTACK
2:    $a \leftarrow$  new array
3:   head  $\leftarrow$  0
4:   procedure PUSH(x)
5:      $a[\text{head}] \leftarrow x$ 
6:     head  $\leftarrow$  head + 1
7:   end procedure
8:   procedure POP
9:     head  $\leftarrow$  head - 1
10:    return  $a[\text{head}]$ 
11:  end procedure
12:  procedure TOP
13:    return  $a[\text{head} - 1]$ 
14:  end procedure
15: end class
```

What is the issue here?

# Resizing Arrays

---

**The Problem:** Arrays are *fixed size!*

- What if we don't know the (maximum) size of the stack in advance?

# Resizing Arrays

---

**The Problem:** Arrays are *fixed size!*

- What if we don't know the (maximum) size of the stack in advance?

**A Solution:** Make a larger array when necessary!

- Must copy contents of old array into new array...  
... this is costly!

Increasing stack capacity

```
1: class ARRAYSTACK
2:    $a \leftarrow$  new array
3:   ...
4:   procedure INCREASECAPACITY( $k$ )
5:      $n \leftarrow$  SIZE( $a$ )
6:      $b \leftarrow$  new array of size  $n + k$ 
7:     for  $i = 0, 1, \dots, n - 1$  do
8:        $b[i] \leftarrow a[i]$ 
9:     end for
10:    head  $\leftarrow b$ 
11:  end procedure
12: end class
```

# Resizing Arrays

---

**The Problem:** Arrays are *fixed size!*

- What if we don't know the (maximum) size of the stack in advance?

**A Solution:** Make a larger array when necessary!

- Must copy contents of old array into new array...  
... this is costly!

Increasing stack capacity

```
1: class ARRAYSTACK
2:    $a \leftarrow$  new array
3:   ...
4:   procedure INCREASECAPACITY( $k$ )
5:      $n \leftarrow$  SIZE( $a$ )
6:      $b \leftarrow$  new array of size  $n + k$ 
7:     for  $i = 0, 1, \dots, n - 1$  do
8:        $b[i] \leftarrow a[i]$ 
9:     end for
10:    head  $\leftarrow b$ 
11:  end procedure
12: end class
```

**Question.** What is the running time of INCREASECAPACITY?

# Two Strategies

---

**Design Question.** When our array runs out of room, by how much should we increase the stack capacity?

**Strategy 1.** Increase the capacity by  $k = 1$  each time.

- Why increase the size more than we need to?

# Two Strategies

---

**Design Question.** When our array runs out of room, by how much should we increase the stack capacity?

**Strategy 1.** Increase the capacity by  $k = 1$  each time.

- Why increase the size more than we need to?

**Strategy 2.** Increase the capacity by  $n$  each time!

- Maybe we'll need more extra space?

# Two Strategies

---

**Strategy 1.** Increase the capacity by  $k = 1$  each time.

- Why increase the size more than we need to?

**Strategy 2.** Increase the capacity by  $n$  each time!

- Maybe we'll need more extra space?

## PollEverywhere Question

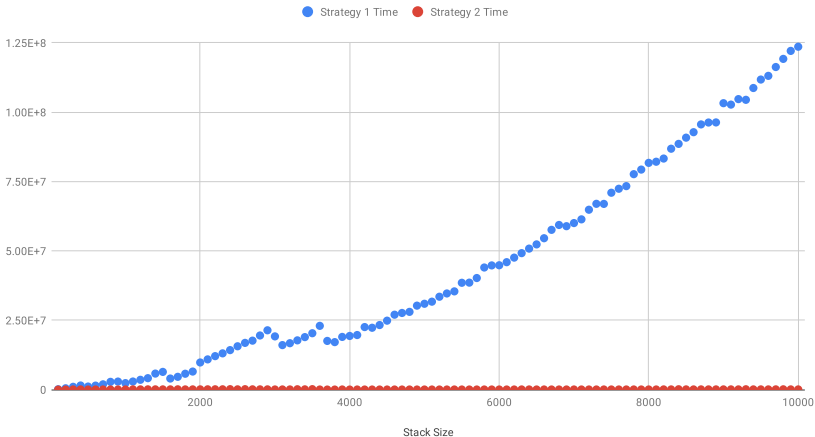

Which strategy will lead to better performance?

[pollev.com/comp526](https://pollev.com/comp526)

# Running Time Comparison

Time to Build Stack (ms)

# Understanding the Discrepancy

---

**Question.** Why was the difference in running time so **dramatic**?

**Observation.** Both strategies have *worst-case* running time of  $\Theta(n)$  for INCREASECAPACITY

- Strategy 1 may incur this on *every* PUSH operation
  - Overall running time  $\Theta(n^2)$

# Understanding the Discrepancy

---

**Question.** Why was the difference in running time so **dramatic**?

**Observation.** Both strategies have *worst-case* running time of  $\Theta(n)$  for INCREASECAPACITY

- Strategy 1 may incur this on *every* PUSH operation
  - Overall running time  $\Theta(n^2)$
- For Strategy 2, INCREASECAPACITY only gets called when the stack size is  $1, 2, 4, 8, \dots, 2^k, \dots, n$ .
  - If cost of resizing  $n'$  is  $c \cdot n'$ , what is total resize cost?

# Amortized Analysis

---

**Goal.** To analyze the worst-case running time of a *sequence* of operations.

- Amortized cost = largest **average** cost per operation averaged over all sequences.

# Amortized Analysis

---

**Goal.** To analyze the worst-case running time of a *sequence* of operations.

- Amortized cost = largest **average** cost per operation averaged over all sequences.

## Banker's View

- Each operation has a (financial) **cost**
- Cost can be paid:
  - from pocket
  - from **bank account**
- For each operation, can
  - withdraw from account
  - deposit to account

# Amortized Analysis

---

**Goal.** To analyze the worst-case running time of a *sequence* of operations.

- Amortized cost = largest **average** cost per operation averaged over all sequences.

## Banker's View

- Each operation has a (financial) **cost**
- Cost can be paid:
  - from pocket
  - from **bank account**
- For each operation, can
  - withdraw from account
  - deposit to account

A sequence of operations has **amortized cost**  $c$  if for each operation:

1. the operation is paid for (from pocket or bank account)
2. at most  $c$  value is paid from pocket and/or *deposited* during each operation

# Amortized Analysis of Strategy 2

---

**Setup.** Suppose we apply Strategy 2 (double the capacity when full):

- PUSH( $x$ ) has cost  $c_1 = O(1)$  if the array is not full,
- PUSH( $x$ ) has cost  $c_2 = O(n)$  if the array is full.

# Amortized Analysis of Strategy 2

---

**Setup.** Suppose we apply Strategy 2 (double the capacity when full):

- $\text{PUSH}(x)$  has cost  $c_1 = O(1)$  if the array is not full,
- $\text{PUSH}(x)$  has cost  $c_2 = O(n)$  if the array is full.

## PollEverywhere Question

How much money must we add to our **bank account** after each (not full) **PUSH** to ensure our balance is at least  $c_2$  before the next resize?

[pollev.com/comp526](https://pollev.com/comp526)

# Amortized Analysis of Strategy 2

---

**Setup.** Suppose we apply Strategy 2 (double the capacity when full):

- PUSH( $x$ ) has cost  $c_1 = O(1)$  if the array is not full,
- PUSH( $x$ ) has cost  $c_2 = O(n)$  if the array is full.

## Completing the analysis:

- If current capacity is  $n$ , last resize was at capacity  $n/2$
- There were (at least)  $n/2$  non-resizing PUSH operations before next resize
- Must pay  $c_2$  for next resize
- It suffices to put  $c_2/(n/2) = 2c_2/n$  in bank each operation

On each non-resizing operation, we pay  $c_1$  out of pocket, and  $2c_2/n$  into the bank

⇒ the amortized cost is  $c_1 + 2c_2/n = O(1) + \frac{1}{n}O(n) = O(1)$ .

**The Moral.** A single resize may cost  $\Theta(n)$ , but the average cost over sequences of operations is always  $O(1)$  (if we're careful).

# The Queue ADT

---

## Queues, Intuitively

Goal: to store a *collection* of elements

- elements arranged as in a queue at Tesco
- new people enter the **back** of the queue
- only the person at the **front** of the queue can be removed (serviced)

# The Queue ADT

---

## Queues, Intuitively

Goal: to store a *collection* of elements

- elements arranged as in a queue at Tesco
- new people enter the **back** of the queue
- only the person at the **front** of the queue can be removed (serviced)

## Queues, Formally

- $S$  is the state of the queue, initially  $S = \emptyset$
- $S.ENQUEUE(x) : S \mapsto xS$
- $S.FRONT() : \text{returns } x_{n-1}$  where  $S = x_0x_1 \cdots x_{n-1}$
- $S.DEQUEUE() : Sx \mapsto S$ , returns  $x$
- $S.EMPTY()$  returns  $TRUE \iff S = \emptyset$

# The Queue ADT

---

## Queues, Intuitively

Goal: to store a *collection* of elements

- elements arranged as in a queue at Tesco

# List Backed Queues

---

## Idea

- Store each element in a NODE
- Store references to NODE:
  - head at the front of the queue
  - tail at the back of the queue

```
1: class LISTQUEUE
2:   NODE head
3:   NODE tail
4:   procedure ENQUEUE(x)
5:     n ← new NODE
6:     n.data ← x
7:     tail.next ← n
8:     tail ← n
9:   end procedure
10:  procedure DEQUEUE
11:    n ← head
12:    head ← n.next
13:    return n.data
14:  end procedure
15: end class
```

# List Backed Queues

---

## Idea

- Store each element in a NODE
- Store references to NODE:
  - head at the front of the queue
  - tail at the back of the queue

## Issues:

- Similar to linked list stack implementation
  - Locality of reference
  - NODE memory overhead

```
1: class LISTQUEUE
2:   NODE head
3:   NODE tail
4:   procedure ENQUEUE(x)
5:     n ← new NODE
6:     n.data ← x
7:     tail.next ← n
8:     tail ← n
9:   end procedure
10:  procedure DEQUEUE
11:    n ← head
12:    head ← n.next
13:    return n.data
14:  end procedure
15: end class
```

# Array Backed Queues

---

## Idea:

- Store elements in the stack in an array
- Maintain indices of head and tail

*Ignores resizing/checking if full*

```
1: class ARRAYQUEUE
2:    $a \leftarrow$  new array, size  $n$ 
3:   head, tail  $\leftarrow$  0
4:   procedure ENQUEUE( $x$ )
5:      $a[\text{tail}] \leftarrow x$ 
6:     tail  $\leftarrow$  tail + 1
7:   end procedure
8:   procedure DEQUEUE
9:     head  $\leftarrow$  head + 1
10:    return  $a[\text{head} - 1]$ 
11:  end procedure
12: end class
```

# Array Backed Queues

---

## Idea:

- Store elements in the stack in an array
- Maintain indices of head and tail

What is the problem here?

*Ignores resizing/checking if full*

```
1: class ARRAYQUEUE
2:    $a \leftarrow$  new array, size  $n$ 
3:   head, tail  $\leftarrow$  0
4:   procedure ENQUEUE( $x$ )
5:      $a[\text{tail}] \leftarrow x$ 
6:     tail  $\leftarrow$  tail + 1
7:   end procedure
8:   procedure DEQUEUE
9:     head  $\leftarrow$  head + 1
10:    return  $a[\text{head} - 1]$ 
11:  end procedure
12: end class
```

# Array Backed Queues

---

## Idea:

- Store elements in the stack in an **array**
- Maintain indices of head and tail

## The fix:

- Use *circular arrays*
- Perform index arithmetic *modulo n* (array size)
- All operations are then  $O(1)$ 
  - **amortized**  $O(1)$  time if resizing by doubling size

*Ignores resizing/checking if full*

```
1: class ARRAYQUEUE
2:    $a \leftarrow$  new array, size  $n$ 
3:   head, tail  $\leftarrow$  0
4:   procedure ENQUEUE( $x$ )
5:      $a[\text{tail}] \leftarrow x$ 
6:     tail  $\leftarrow$  tail + 1 mod  $n$ 
7:   end procedure
8:   procedure DEQUEUE
9:     head  $\leftarrow$  head + 1 mod  $n$ 
10:    return  $a[\text{head} - 1 \bmod n]$ 
11:  end procedure
12: end class
```

# The (Min) Priority Queue ADT

---

## Priority Queues, Intuitively

Goal: to store a *collection* of elements

- Each element  $x$  has an associated *priority*,  $p(x)$
- New elements **inserted** with prescribed priorities
- Can access/remove element with the *minimum* priority in the collection

# The (Min) Priority Queue ADT

---

## Priority Queues, Intuitively

Goal: to store a *collection* of elements

- Each element  $x$  has an associated *priority*,  $p(x)$
- New elements **inserted** with prescribed priorities
- Can access/remove element with the *minimum* priority in the collection

## Priority Queues, Formally

- $S$  is the state of the queue, initially  $S = \emptyset$
- $S.\text{INSERT}(x, p(x)) : S \mapsto xS$
- $S.\text{MIN}() : \text{returns } x_0$  where  $S = x_0x_1 \cdots x_{n-1}$
- $S.\text{REMOVEMIN}() : xS \mapsto S$ , returns  $x$
- $S.\text{DECREASEKEY}(x, p')$   
 $S = x_0x_1 \cdots x_{i-1}xx_{i+1} \cdots x_{n-1} \mapsto x_0x_1 \cdots x_{j-1}xx_jx_{i-1}x_{i+1} \cdots x_{n-1}$ 
  - $p(x_j) \leq p'(x) < p(x_{j+1})$

# The (Min) Priority Queue ADT

---

## Priority Queues, Intuitively

Goal: to store a *collection* of elements

- Each element  $x$  has an associated *priority*,  $p(x)$
- New elements **inserted** with prescribed priorities
- Can access/remove element with the *minimum* priority in the collection

## For Next Time

- Think about implementing min priority queues with linked lists and stacks
- Consider the running times of the priority queue operations

## Priority Queues, Formally

- $S$  is the state of the queue, initially  $S = \emptyset$
- $S.\text{INSERT}(x, p(x)) : S \mapsto xS$
- $S.\text{MIN}() : \text{returns } x_0 \text{ where } S = x_0x_1 \cdots x_{n-1}$
- $S.\text{REMOVEMIN}() : xS \mapsto S, \text{ returns } x$
- $S.\text{DECREASEKEY}(x, p')$   
 $S = x_0x_1 \cdots x_{i-1}xx_{i+1} \cdots x_{n-1} \mapsto x_0x_1 \cdots x_{j-1}xx_jx_{i-1}x_{i+1} \cdots x_{n-1}$ 
  - $p(x_j) \leq p'(x) < p(x_{j+1})$

## Next Time: Trees!

---

- Heaps
- Binary Search Trees
- Balanced Binary Trees

# Scratch Notes
